The EX80-Series are electromagnetic insertion flow sensors for use in conductive liquids in pipe sizes 1” to 10” (25mm to 250 mm.) Lacking moving parts, they are well suited for applications with particulates in the fluid that are problematic for impellers or turbines. Other advantages are insensitivity to viscosity and tolerance for pulsating flows such as with air-driven diaphragm pumps.

Modularity. Simplicity and modularity are at the core of the EX80 design. The basic flow sensor has one output, which is pulse proportional to flow rate. The FT420 module can be added to provide indication, 4-20 mA, and flow rate setpoints. The A055 adds 4-20 mA analog only (blind transmitter). The FS30 is a flow switch module, and the DL75 is a datalogger. Any of these modules can be ordered pre-installed on the flow sensor or in a wall mount housing, and any can be retrofitted to the EX80-Series sensor in the field. The EX80 is also compatible with the FT520 batching flow processor.

Output. The basic pulse signal is compatible with many controls, with PLC’s and irrigation or water treatment controllers being the most common. For these applications it is sometimes necessary to add a pull-up resistor, if the controller is not designed for a current-sinking input. See the section on “Connecting to PLC’s and other Controllers” before connecting to a non-SeaMetrics control.

Insertion Depth. Like all insertion flow sensors, the EX80-Series extend into the pipe and measure the velocity of the fluid in a particular area of the pipe. The chosen insertion depth is the “critical point”, or the area of the flow stream which maintains the average velocity across a wide range of flow rates. This is necessary because the shape of the velocity profile changes as the rate increases. (It transitions from a “bullet” to more of a “plug” shape).

Fittings. Since the EX80-Series sensors are not adjustable, they must be purchased with fittings appropriate to the application. The EX81 is sized for fittings of 1” to 3”. The EX82 is for fittings of 4” to 10”. Each fitting insures that the flow sensor is installed at the correct point. Every flow sensor and every tee fitting is wet calibrated. Saddle fittings are normally not wet calibrated, because they are field-installed on a pipe. In PVC however it is possible to order a saddle pre-installed on a standard length of pipe, in which case the entire assembly is wet-calibrated. For all other saddles, the K-factor (pulses per gallon), established through testing with various standard schedules of pipe, is provided with the saddle.

Fitting Installation. EX80 Series meters require special fittings. The meter fitting must first be installed in the pipeline. Straight pipe of at least ten times the diameter upstream of the meter and five diameters downstream is strongly recommended in order to achieve proper accuracy. These are minimum values. As the diagrams on the next page will show, you may need more straight run under specific adverse circumstances.

If you can’t provide enough run to smooth out the turbulence caused by valves, fittings, and changes in direction, some decrease in accuracy may result. This does not mean that the flow meter’s reading is meaningless, however. In some applications (for instance, where the flow meter is part of a control system, operating a valve or controlling chemical addition), a repeatable reading may be more important than a highly accurate one.

EX80 Series PVC meter tees are supplied with some upstream straight pipe. The length provided may be less than ten diameters upstream and five downstream. It is not advisable to connect directly to the end of these fittings with a flow-disturbing device such as a valve or elbow. If possible, straight pipe should be added to the upstream end of these fittings.

A PVC fitting is usually installed by solvent welding. The stainless steel and brass meter fittings have female pipe threads, requiring the appropriate male threaded fittings. Saddle fittings (size 3” and above) require a hole to be cut in the pipe. The recommended hole size is 1-3/4”.

**Meter Installation.** After the meter fitting is installed in the pipeline, the meter can be installed in the fitting. After noting the direction of the flow arrow, press the meter into the fitting as far as it will go. Retain the meter in place by inserting the u-pin. The pin can be installed from either side. It may be necessary to rotate the probe back and forth slightly to start the pin into the slots on the probe. Slide the pin in as far as it will go.

**POSITIONING THE METER**

Okay position if there is no air in the pipe.

Examine the flow profile to ensure that the flow is not distorted. Distorted flows can cause the meter to read high or low.

A 10X Diameter Minimum (See Below)

**Caution:** Never remove the u-clip retainer when the pipe is under pressure. Always remove pressure from the pipe before you attempt to remove the meter. Removal under pressure may result in damage or serious injury.

Two Elbows, Out Of Plane

Expanded Pipe

Spiral Flow

Propeller Meter

Swirling Flow

Partially Open Butterfly Valve
Caution: These flow sensors are not recommended for installation downstream of the boiler feedwater pump where installation fault may expose the flow sensor to boiler pressure and temperature. Maximum recommended temperature is 130°F (Plastic), 200°F (Metal).
**ELECTRICAL CONNECTIONS**

**General Electrical Guidelines:**
- Whenever possible avoid running control cables in the same conduit with AC power.
- Using shielded cable, be sure that one end is grounded.
- Avoid routing flow sensor cables in close proximity to a variable frequency drive.
- Recommended power and output wiring is shielded 18-22 AWG control cable.
- Recommended voltage is 12-24 VDC. Note that unregulated power supplies can vary from nameplate voltage by a considerable amount. When in doubt, use a regulated power supply.

See the Connections diagrams on the following pages for the appropriate terminals.

**Power:** A 12 - 24 Vdc power supply capable of at least 250 mA current output is needed.

**Forward Flow Output:** This open-collector isolated output does not supply power. This pulse is generated in the forward flow direction on the standard unit. (Reverse flow output is available as an option).

**Note:** This output is limited to 6 mA at 30 Vdc maximum.

**Reverse Flow Output:** Reverse flow output is available as an option. This open-collector isolated output does not supply power. It functions like a polarity-sensitive switch closure.

**Note:** This output is limited to 6 mA at 30 Vdc maximum.

**Grounding Guidelines:**

For best results, use a good quality earth ground, such as metallic water piping, or a stake driven into the ground.

If the flow sensor is installed in metallic piping, for optimum grounding clamp wires to the piping a short distance to either side of the flow sensor using hose type clamps. Connect these wires to the earth ground and to one of the housing screws. (For non-metallic piping, this step is not needed.)

EX meters are usually unaffected by moderate levels of electrical noise. In some applications performance may be improved by taking the following steps:
- Use shielded twisted pair cable (Belden 8723 or equivalent above ground or Alpha 35482 or equivalent burial).
- Clamp a ferrite bead (Steward 28A2029-OAO or equivalent) on meter signal/power wire within 3/4” of the meter strain relief (tape or tie wrap in place if necessary). See diagram below.
- **IMPORTANT** - Connect the cable shield ground wire to ground, ONLY at power supply end of cable.

OPERATION & MAINTENANCE

Zero Adjustment. When the EX81 or 82 is powered up and there is no flow, there should be no output pulses (or, if connected to the FT420, flow rate should read “0”). If there are pulses it may be necessary to adjust the flow meter under no-flow conditions after it has been installed. This should only be done if the indicated flow is low, near the lower cutoff.

To perform the adjustment, after determining that there is a full pipe with no flow, short between the two pins marked “Zero Adjust”. A red LED light will come on for approximately 50 seconds and then go out. The zero adjustment is completed.

Minimum Flow. As with any other flow sensor, there is a rate below which the EX80-series sensor cannot read. Check the flow rate table below for the minimum flow rate detectable by the sensor for a given pipe size.

Completion of Zero Adjustment

Electrode Coating. Grease or other adhering, non-conductive materials can stop flow detection if the electrodes become heavily coated. To clean the electrodes, remove the sensor from the pipe and gently scrub the electrodes (three silver bumps) on the reading face of the flow sensor. A mild soap (dishwashing liquid for example) can be used to aid the cleaning process.

Calibration (“K-factor”). The K-factor represents the actual number of pulses per gallon the meter produces during a flow test. This number can be entered into your electronic control to make it read properly. If the EX80 Series meter is ordered with a tee fitting, it is factory-calibrated in the fitting and the K-factor is indicated on the side of the fitting (see diagram).

If the EX80 Series meter is ordered with a saddle or weldolet fitting, find your K-factor in the chart below.
